Aim: Practical based on Pandas Data Structures

IDE:

What is Python Pandas?

Pandas is a powerful, open-source data analysis and manipulation package for Python. It provides data structures and functions needed to work on structured data seamlessly and efficiently.

What Is Pandas Used For?

Pandas is extensively used for:

- Data Cleaning: Handling missing values, duplications, and incorrect data formats.
- Data Manipulation: Filtering, transforming, and merging datasets.
- Data Analysis: Performing statistical analysis and aggregations.
- Data Visualization: Creating plots and charts to visualize data trends and patterns.
- Time Series Analysis: Handling and manipulating time series data.

Run the following command to install Pandas:

```
pip install pandas
```

```
import pandas as pd
```

```
print(pd.__version__)
```

Pandas Series

A Pandas Series is a one-dimensional labeled array capable of holding any data type. It is similar to a column in a spreadsheet or a SQL table.

Example:

```
import pandas as pd
# Creating a Series
data = [1, 2, 3, 4, 5]
series = pd.Series(data)
print(series)
```

Output:

Pandas DataFrame is two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns). A Data frame is a two-dimensional data structure, i.e., data is aligned in a tabular fashion in rows and columns. Pandas DataFrame consists of three principal components, the data, rows, and columns.

Creating a DataFrame

```
data = {
    'Name': ['Alice', 'Bob', 'Charlie'],
    'Age': [25, 30, 35],
    'City': ['New York', 'Los Angeles', 'Chicago']
}
df = pd.DataFrame(data)
print(df)
Output
```

Subject: Programming With Python (01CT1309)	Aim: Practical based on Pandas Data Structures
Experiment No: 09	Date: Enrollment No:92400133189

```

1  import pandas as pd
2
3  data = {
4      'Name': ['Alice', 'Bob', 'Charlie'],
5      'Age': [25, 30, 35],
6      'City': ['New York', 'Los Angeles', 'Chicago']
7  }
8
9  df = pd.DataFrame(data)
10 print(df)

```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL

```

1      Bob    30  Los Angeles
2  Charlie    35    Chicago

```

Basic Operations on Dataframes

DataFrames support a wide range of operations for data manipulation and analysis.

```

# Accessing Columns (# select one column)
print(df[['Name']])

```

Output

example.py > ...

```
6         'City': ['New York', 'Los Angeles', 'Chicag
7     }
8
9     df = pd.DataFrame(data)
10    df['Salary'] = [70000, 80000, 90000]
11    print(df)
```

The DataFrame is like a table with rows and columns.

Pandas use the loc attribute to return one or more specified row(s)

Return row 0:

```
print(df.loc[[0]])
```

Output

```

9  df = pd.DataFrame(data)
10 df['Salary'] = [70000, 80000, 90000]
11 print(df)
12 df = df.drop('City', axis=1)
13 print(df)
14 print(df.loc[[0]])

Named Indexes

With the index argument, you can name your own indexes.

Example:

Add a list of names to give each row a name:

import pandas as pd

data = {

 "calories": [420, 380, 390],

 "duration": [50, 40, 45]

}

df = pd.DataFrame(data, index = ["day1", "day2", "day3"])

print(df)

Output

```

2  data = {
3      "calories": [420, 380, 390],
4      "duration": [50, 40, 45]
5  }
6  df = pd.DataFrame(data, index = ["day1", "day2", "day3"])
7  print(df)
8

```

Data Inspection:

`df.head()` : Display the first few rows of the DataFrame.

`df.tail()` : Display the last few rows of the DataFrame.

`df.info()` : Display a summary of the DataFrame.

`df.describe()` : Provide descriptive statistics for numerical columns. (count: the number of non-null entries, mean: the mean value, std: the standard deviation, min: the minimum value, 25%, 50%, 75%: the lower, median, and upper quartiles, max: the maximum value)

Example:

```
dat = pd.read_csv("data.csv")
print(dat.info())
# shows first and last five rows
print(dat.head())
print(dat.tail())
print(dat.describe())
```
